

# Probing and overcoming KRAS<sup>G12C</sup> inhibitor resistance by combination with a pan-KRAS SOS1 inhibitor

#### Introduction

The recent accelerated approval of the KRASG12C mutantselective inhibitor Sotorasib (AMG 510) for the treatment of 2<sup>nd</sup> line *KRAS<sup>G12C</sup>* mutation-positive NSCLC patients marks the first approved targeted therapy for tumors with any KRAS mutation. While KRAS<sup>G12C</sup> inhibitors deliver clinical benefit, most patients who achieved an objective response ultimately progressed. Recent insights into clinical KRASG12C inhibitor resistance identified reactivation of the RAS/MAPK pathway as a common putative driver mechanism of resistance. Multiple ongoing trials seek to augment responses to KRAS<sup>G12C</sup> inhibitors through rational combination strategies, including the SOS1::KRAS inhibitor BI 1701963.

Here we use different preclinical experimental approaches to interrogate KRAS<sup>G12C</sup> inhibitor resistance mechanisms with the aim to identify strategies to overcome resistance. To predict on-target resistance,

- Ba/F3 cells were transduced with *KRAS<sup>G12C</sup>*, ENU-mutagenized and chronically exposed to KRAS<sup>G12C</sup> inhibitors. Resistant clones were screened for secondary KRAS mutations, highlighting that KRAS G12C/Y96D and Y96S cis mutations did confer resistance to KRAS<sup>G12C</sup> inhibition but could be overcome by combining a MEK inhibitor with a SOS1 inhibitor.
- As second strategy a high-complexity single site variant library of KRAS<sup>G12C</sup> encompassing all possible secondary KRAS mutations was employed to establish Ba/F3 transgenic cell pools. The response of this KRAS<sup>G12C</sup> Ba/F3 clone library harboring a comprehensive set of secondary mutations was tested following treatment with KRAS<sup>G12C</sup> inhibitors alone and in combination with a pan-KRAS SOS1 inhibitor. In parallel, acquired KRAS<sup>G12C</sup> inhibitor resistance was generated in solid cancer cell lines following long-term Adagrasib (MRTX849) treatment. Clones were characterized and their response to KRAS<sup>G12C</sup> inhibition and combination therapy was analyzed. Both in the Ba/F3 cell pool as well as in KRAS<sup>G12C</sup> inhibitor resistant solid cancer clones, combining SOS1 inhibition with KRAS<sup>G12C</sup> inhibition suppressed the incidence of resistant growth.
- Finally, probing resistance in vivo, SW837 (CRC) tumor-bearing mice were subjected to long-term treatment with Adagrasib until tumors relapsed after initial regression. Resistant tumors were randomized for second line treatments. In this KRAS<sup>G12C</sup> inhibitor resistant setting, treatment with Adagrasib plus Cetuxi mab resulted in tumor stasis while a dagrasib plus SOS1i resulted in tumor regressions.

### Strategy to Overcome KRAS<sup>G12C</sup>i Resistance

### Key findings and conclusions

While more work is currently being undertaken to map the resistance mechanisms in both our in vitro and in vivo settings, the results highlight the potential of combining a SOS1 inhibitor with a KRAS<sup>G12C</sup> inhibitor to prevent and/or overcome acquired resistance.

The pan-KRAS SOS1 inhibitor BI 1701963 is the first direct RAS signaling modifier in phase I clinical trials both as a monotherapy as well as in combination with KRAS<sup>G12C</sup> inhibitors.
